### Reconfigurable Flight Control Design using a Robust Servo LQR and Radial Basis Function Neural Networks

John J. Burken NASA Dryden Flight Research Center

IJCNN 2005 International Joint Conference on Neural Networks July 31 – August 5, 2005

ICCNN, Montreal Canada August 2005

## Reconfiguration

### **Presentation Outline**

- Purpose
- Background
- Design Methods Used for Paper
  - ➤ Background on Model Reference Adaptive Control (MRAC)
  - ➤ Background on Robust Servomechanism LQR
  - ➤ Radial Basis Function Neural Networks
- Control Failure Survivability Results
- Results / Time Histories
- Conclusions
  - ➤ Remarks
  - ➤ Lessons Learned

## Control Reconfiguration

### **General Background / Concepts**

- Purpose of Reconfigurable Control / Why?
  - ➤ Handle Failures & Land Safely
  - **➤** Continue on with Mission
  - ➤ Buy More Time to Terminate Flight at a Better Location (UAV)
- Overall Controller Objective.
  - ➤ Maintain consistent stable performance in the presence uncertainties and unmodeled dynamics.

## Control Reconfiguration

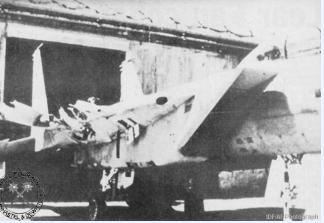

### **General Background / Concepts**

- Why Adaptive Control.
  - Handles Uncertainties and unpredicted parameter deviations.
  - Adaptive control is better than Robust Control w.r.t. slow varying parameters.
- Why Robust Control (Such as Robust LQR servo design)
  - ➤ Handles fast varying parameters and unmodeled dynamics.
  - Has good flight experience.
- Solution to Adaptive & Robust control issues.
  - ➤ Merge Adaptive augmentation into a Robust Baseline Controller.

## **Reconfiguration Flight Control Systems**

- Motivation / Problem Statement {The Big Picture}
  - · Land a damaged airplane or, return to a safe ejection site.
- Or continue with mission
- General Goals & Objectives
  - Flight evaluation of neural net software.
  - · Increased survivability in the presence of failures or aircraft damage.
    - · Increase your boundary of a flyable airplane.
    - Increase your chances to see another day.
    - · Increase your chances to continue the mission.

### Motivation, cont

Airplanes in the Past Have Landed with Major Failures.

 But possibly not as many safe landings as could have, with adaptive control methods.

Our Goal is to Increase the Survivability Region for the Pilot without luck or high skill levels or when the pilot is injured.

## Flight Control??

- How do we Reconfigure the Controller (called H or K)
  - Many ways to adapt to a failure or unknown Plant (G) parameters:
    - → Adaptation Methods:
      - → Non-Learning Methods:
        - → Robust Reconfiguration Methods.
        - → Fault detection & isolation.
        - → Use of smart actuators (Handles only B matrix failures).
        - → Reconfigurable Retrofit Architecture methods.
      - → Learning Methods:
        - → Use of Neural networks
        - → To many to list (such as RBF Radial Basis Function)

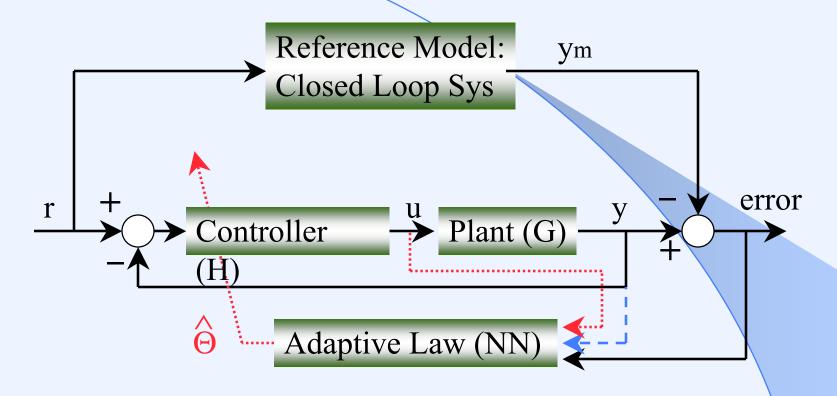

### General Statements on Adaptive Controller

- Two Types of Adaptive controllers
  - 1. Direct Adaptive
  - 2. Indirect Adaptive
- The Direct Adaptive Controller Works on the Errors.
  - Needs a Reference Model to Generate P\_err = (P\_cmd-Psensor)
  - The Neural Network "Directly" Adapts to P\_err.
  - Does not need to know the source of error.
    - No Aero Parameter Estimation Needed
    - No need for persistently exciting signals
- The Indirect Adaptive Works on Identifying the source of Error.
  - Does Not Need a Reference Model.
  - Needs to Identify the Aerodynamics that have changed! (PID)
    - PID is Time Consuming and *may not* be correct.
    - Needs persistently exciting inputs.

### Model Reference Adaptive Control (MRAC)

- Plant: Actual Plant parameters (G) are unknown.
- Reference Model: Ideal response (ym) to cmd r (Use a Stable Reference Model).
- Adaptation Law: Is used to adjust controller (H): can be NNs.

### Servomechanism Design Methodology

### **Consider a MIMO system**

$$\dot{X} = Ax + Bu + Ew$$
 where  $x \in R^n$ ,  $u \in R^m$ ,  $y \in R^p$ 

$$Y = Cx + Du + Fw$$

**w** = the disturbance (failed surface)

The dynamic controller is

$$\dot{\mathbf{x}}_{c} = \mathbf{A}_{c}\mathbf{x}_{c} + \mathbf{B}_{c}(\mathbf{r} - \mathbf{y})$$

The open loop augmented system is

$$\begin{bmatrix} \dot{\mathbf{x}} \\ \dot{\mathbf{x}} \\ \dot{\mathbf{c}} \end{bmatrix} = \begin{bmatrix} \mathbf{A} & \mathbf{0} \\ -\mathbf{B}_{c}\mathbf{C} & \mathbf{A}_{c} \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ \mathbf{x}_{c} \end{bmatrix} + \begin{bmatrix} \mathbf{B} \\ -\mathbf{B}_{c}\mathbf{D} \end{bmatrix} \mathbf{U}$$

#### Note:

- ① LQR Servo = LQR PI
- ①Jammed or failed surface is treated as a disturbance to the system.
- 2 Approach is simple to implement.

Suppose the following condition is satisfied

$$rank \begin{bmatrix} \ddot{e}_i I - A & B \\ -C & D \end{bmatrix} = n + p$$

The system is controllable and there exist a control law

$$\mathbf{u} = \mathbf{k}\mathbf{x} + \mathbf{k}_{\mathbf{c}}\mathbf{x}_{\mathbf{c}}$$

If this statement is true there exist a closed-loop system that is stable.

### Servomechanism Design Methodology (cont.)

- Remarks:
- For any such control law, asymptotic tracking and disturbance rejection are achieved; that is, the error goes to zero.
- If the augmented system is controllable, the control law can be conveniently found by applying the linear quadratic regulator (LQR) approach to the augmented system.
- After setting up the augmentation we now need to  $\begin{bmatrix} \dot{x} \\ \dot{x} \\ x_c \end{bmatrix} = \begin{bmatrix} A & 0 & x \\ -B_c & A_c & x_c \end{bmatrix} + \begin{bmatrix} B \\ -B_c & D \end{bmatrix} U$ solve for the gain (k, kc)
  - ➤ Just use LQR.
  - ➤ This setup allows for a LQR tracker solution.

Control Law  $u = kx + k_c x_c$  $e = r - y \rightarrow 0$ 

The augmented system is

$$\begin{bmatrix} \dot{\mathbf{x}} \\ \dot{\mathbf{x}} \\ \vdots \\ \mathbf{X}_{c} \end{bmatrix} = \begin{bmatrix} \mathbf{A} & \mathbf{0} \\ -\mathbf{B}_{c}\mathbf{C} & \mathbf{A}_{c} \end{bmatrix} \begin{bmatrix} \mathbf{x} \\ \mathbf{x}_{c} \end{bmatrix} + \begin{bmatrix} \mathbf{B} \\ -\mathbf{B}_{c}\mathbf{D} \end{bmatrix} \mathbf{U}$$

### Servomechanism Design Methodology (cont.)

Optimize the following cost function.
 Optimal linear-quadratic-regulator (LQR) problem.

$$J = \int_0^T (x'Qx + u'Ru)dt$$

• The algebraic Riccati equation

$$0 = A'P + PA + Q - PBR^{-1}B'P$$

• And the optimal control is given by:

$$u(t) = -R^{-1}B'Px(t) = Kx(t)$$

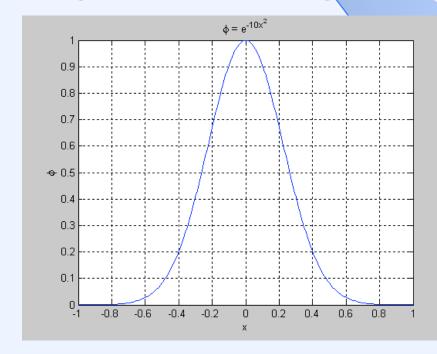

## Why Neural Networks?

- -Neural Networks are Universal Approximators.
- -Minimizes a H<sup>2</sup> norm.
- -They permit a nonlinear parameterization of uncertainty.
- –Why Radial Basis Functions (RBF):
  - -RBFs will de-activate when signal is outside "neighborhood".

Activation function

$$-\left[\frac{\left\|x-r\right\|^2}{2\sigma}\right]$$

$$\phi(x) = e^{-\left[\frac{\left\|x-r\right\|^2}{2\sigma}\right]}$$

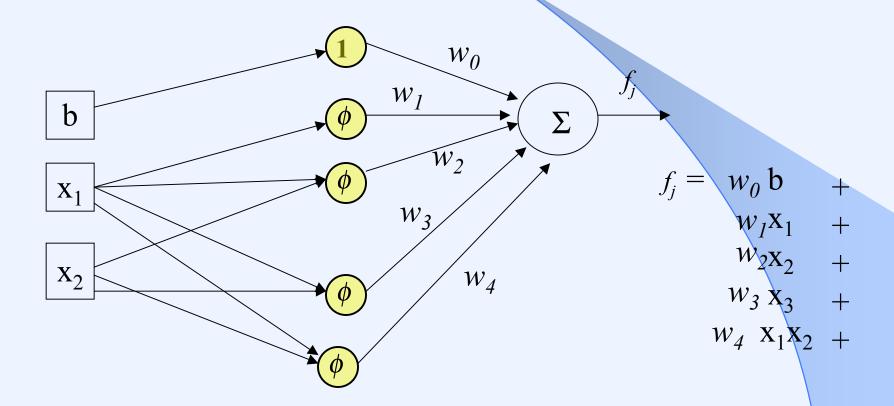

## **RBF** Network Outputs

- The output of a RBF network with K neurons:
  - $\rightarrow$   $\phi_k(x)$  is the response of the kth hidden neuron for input vector x.
  - $\succ$   $w_k$  is the connecting weight of the output neuron.

$$f(x) = NN(x) = \sum_{k=1}^{K} w_k \phi_k(x) + b$$

# Neurons 1 Hidden layer with 4 Neurons and 2 Inputs

 $\phi$  means activation function

# Failures Investigated

2 groups of failures are "common" among aircraft mishaps/crashes.

- Aerodynamic Failures or uncertainties (A Matrix problems / lost aero surfaces, bent wings)
  - Or Not well known aero terms due to modelling errors.
- Control Failures (B Matrix problems / jammed control surfaces)
  - Right stab jammed at 8. deg from trim

## Control Reconfiguration Results

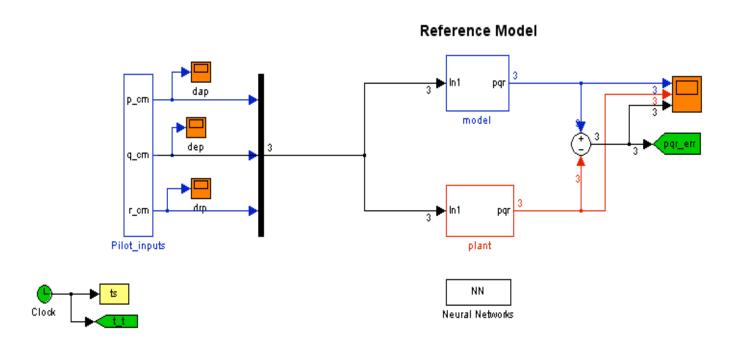

- Time History of Surface Failure (B matrix)
- Failure = Right Stabilator Jammed.
  - ➤ At time = 10 seconds / 8 deg from trim.
  - ➤ At time = 30 seconds Failure goes away (crew fixed the failure).
- Neural Networks
  - > Neural Networks turned off for the first run.
  - > Neural Networks turned on for second run.
  - ➤ Without Dead Zones.

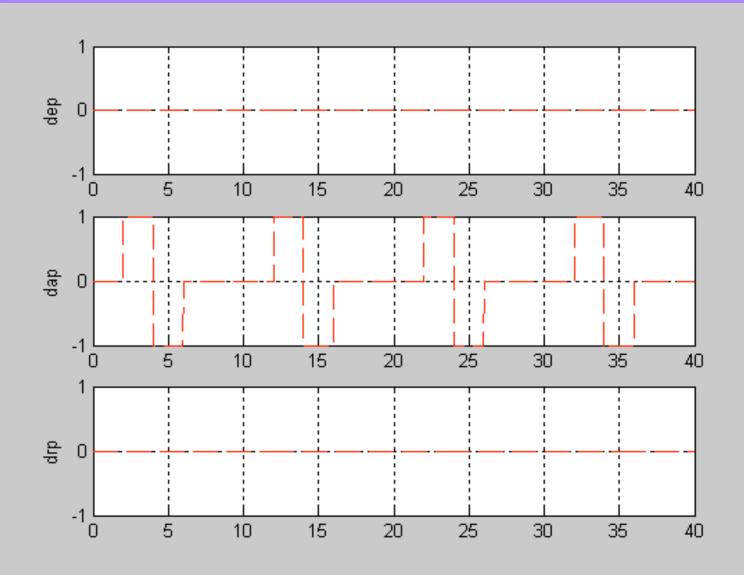

# Robust Model Reference Adaptive Control Design

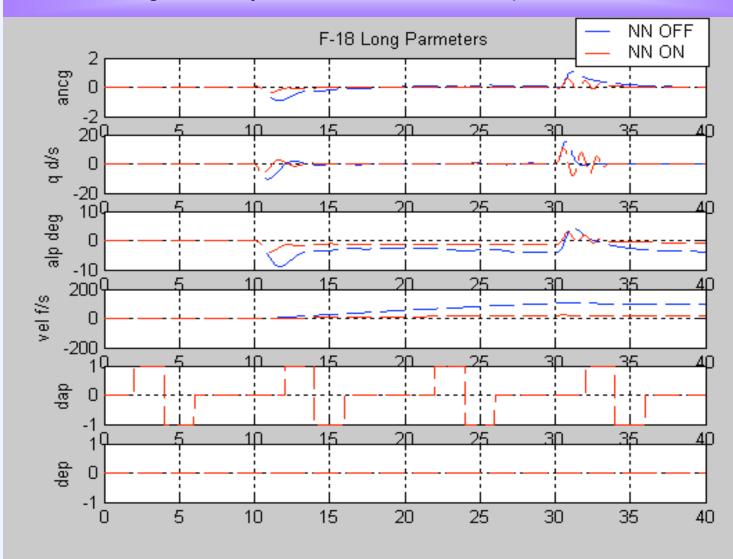

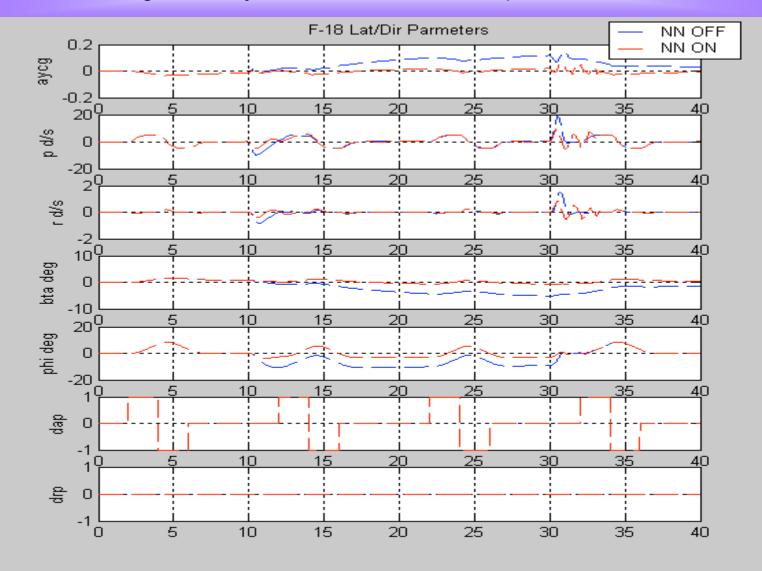

F-18 LQR-Tracker (Robust Servo LQR)
Model Reference Adaptive Control System Design

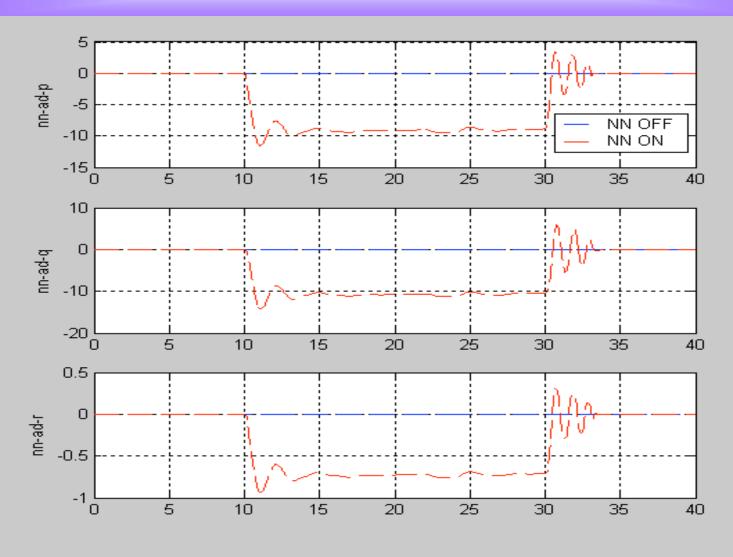

March 01, 2005

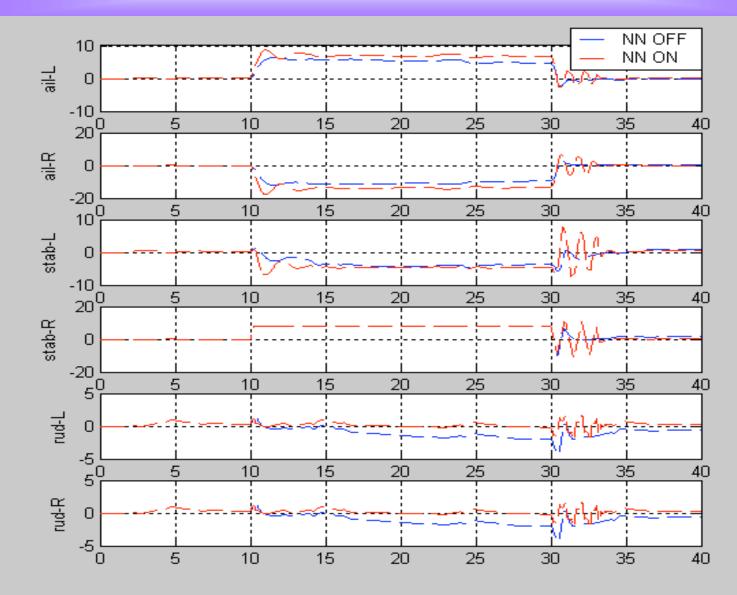

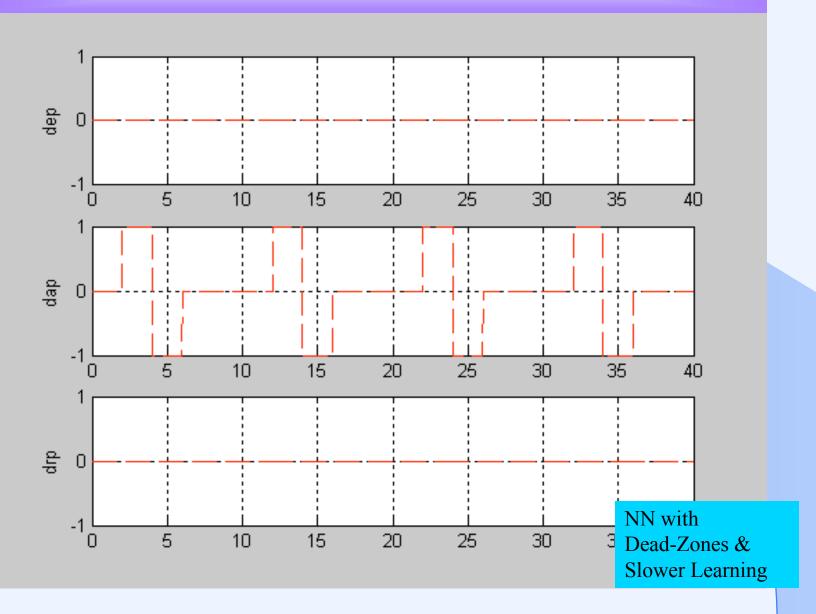

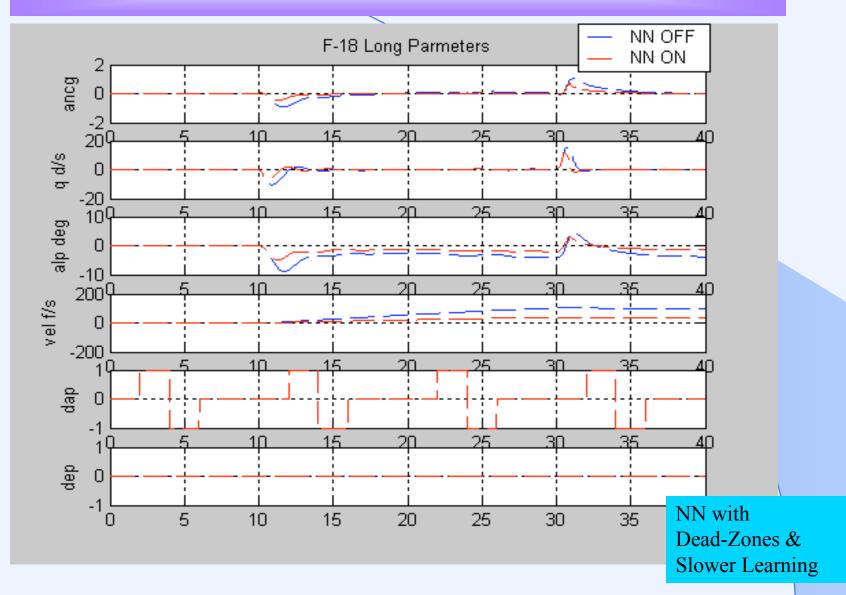

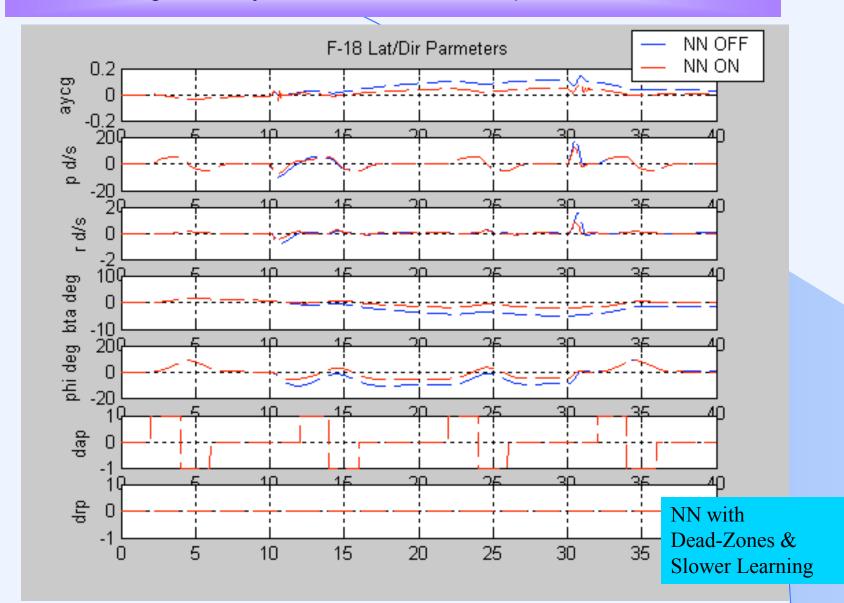

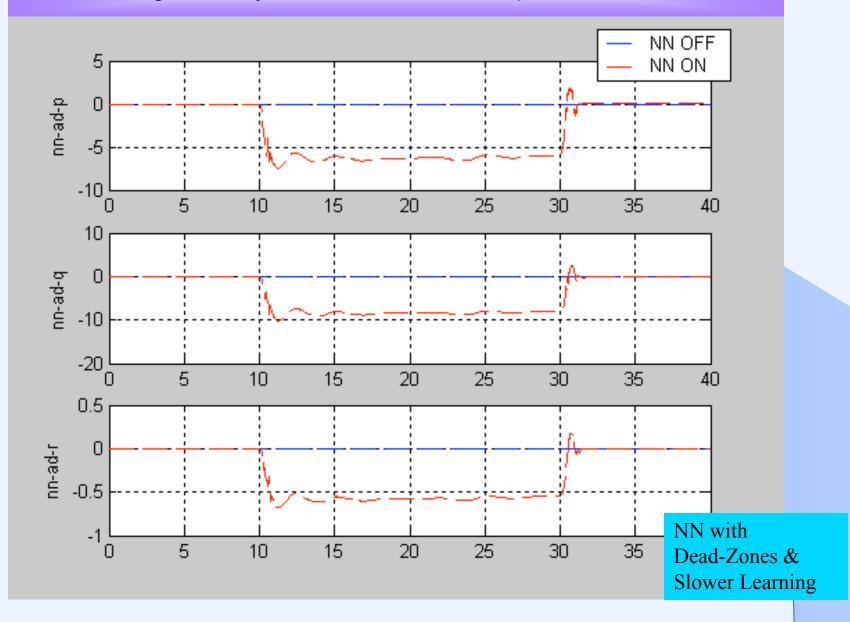

## Control Reconfiguration Results

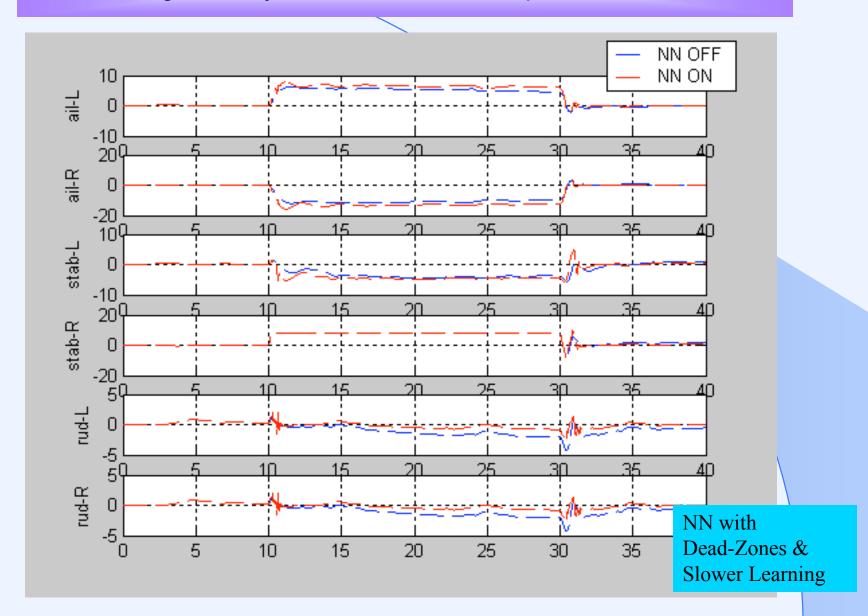

- Time History of Surface Failure (B matrix)
- Failure = Right Stabilator Jammed.
  - ➤ At time = 10 seconds / 8 deg from trim.
  - ➤ At time = 30 seconds Failure goes away (crew fixed the failure).
- Neural Networks
  - > Neural Networks turned off for the first run.
  - > Neural Networks turned on for second run.
  - ➤ With Dead Zones & 20% decrease in learning rates.

### Control Reconfiguration Conclusions

#### Conclusions & Remarks

- Method presented:
  - ➤ Robust LQR Servomechanism design with Model Reference Adaptive Control
    - → Reference Model was a "health" aircraft.
  - Used Radial Basis Function Neural Networks
- Results:
  - > LQR Servomechanism behaved well with a failure.
  - Using the Neural Networks improved the tracking compared to not using the neural networks.
- Lesson learned:
  - Test the removal of the failure with Neural Networks active to ensure good performance.
    - → The crew could fix the problems and you don't want the adaptive system to go unstable.
